In the late 1980s, we projected future employment in scores of occupations for the 1988-2000 period. That future is now the past. See where we scored a hit, landed in the ballpark, and—now and then—swung and missed.

**They've crunched the final numbers** and analyzed each occupation. They've published the latest edition of the *Occupational Outlook Handbook*. Economists in the Bureau of Labor Statistics' (BLS) employment projections program have wrapped up another set of projections; their work is done. Or is it?

The last phase of the projections process is evaluating the projections after actual data are available. And so, when employment data for 2000 became available, it was time to analyze the 1988-2000 employment projections—the basis for the 1990-91 *Handbook.* Evaluating past employment projections serves two purposes. First, projections users—such as career guidance counselors, jobseekers, and students—can assess the reliability of current information based on BLS' track record. Second, identifying

Andrew Alpert and Jill Auyer are economists in the Office of Occupational Statistics and Employment Projections, BLS, (202) 691-5754 and (202) 691-5806, respectively.

errors and biases in past projections enables BLS economists to improve the accuracy of subsequent projections.

This article compares projected outlook with actual employment for selected occupations, identifies sources of error in developing the projections, and assesses the overall reliability of BLS job outlook information. A box on page 9 explains the employment projections process, including the evaluation stage. The table beginning on page 12 provides a comparison of projected and actual employment data for more than 300 occupations for which projections were developed.

### Comparing projected with actual employment

The 1988–2000 occupational employment projections covered 491 occupations. These projections were the basis for job outlook information in the 1990–91 *Occupational Outlook Handbook*, which included about 250 detailed occupations. This evaluation includes information on 338 of the occupations for which projections were developed.

#### **Growth descriptors**

Growth descriptors give readers a general impression of the job outlook for each occupation. In most cases, it is not necessary to have an exact match between the projected and actual growth descriptors to get an accurate view of employment growth. For example, employment of accountants and auditors was projected to grow faster than average but actually grew at an average rate. The assumptions about the causes of growth were most likely correct; however, their effects on employment were overestimated.

The following growth descriptors were used to describe ranges of employment growth or decline between 1988 and 2000:

Growth descriptor	Projected employment change,1988-2000
Much faster than average	Increase 31 percent or more
Faster than average	Increase 20 to 30 percent
About as fast as average	Increase 11 to 19 percent
More slowly than average	Increase 4 to 10 percent
Little or no change	Increase or decrease 3 percent or less
Decline	Decrease 4 percent or more

Because the adjectives describing growth are based on established numerical cutoffs, the descriptors for many

occupations would have been different if the numerical projection had been 1 or 2 percentage points higher or lower. This sensitivity sometimes caused projected and actual descriptors to differ when projected and actual employment levels were close.

**Analyzing descriptors.** The *Handbook* does not include all occupations for which employment is projected. However, all 338 occupations included in this evaluation were analyzed by their growth adjective, regardless of whether they appeared in the *Handbook*. Growth descriptors based on projected employment change were compared with descriptors corresponding to actual growth. Of the 338 occupations in this evaluation, 87 had actual employment changes that matched the projected adjective; another 100 had employment changes that were one category higher or lower. Twelve occupations had employment changes that were five categories away. In these cases, the occupation was either projected to grow much faster than average and actually declined or was projected to decline and actually grew much faster than average.

The 1988-2000 projections, like past projections, are conservative; this is evident in the distribution of projected and actual growth adjectives. Average growth was the most common projection of employment for occupations, but most occupations had employment that actually either grew much faster than the average or declined. About 30 percent of the occupations were projected to have average growth, but about 15 percent actually did. Slightly more than 26 percent of the occupations were projected to either grow faster than the average or decline; however, 57 percent of the occupations fell into 1 of these 2 categories.

The growth categories of much faster than average and declining were most accurate in terms of the number of occupations that actually fell into their projected categories. More than 65 percent of occupations projected to grow much faster than average, and half of the occupations projected to decline, actually fell into their respective categories. About 21 percent of occupations that were projected to have average growth actually had average growth. The higher degree of accuracy in the extreme growth categories suggests that the accuracy of projections is greatest where there is either a strong growth or a strong decline in occupational trends.

Fastest growing occupations. Greater accuracy in the extreme growth categories is evident in the 20 fastest growing occupations. All of these occupations were projected to have much faster than average growth, and employment in all but five of them actually grew much faster than average. In many cases, the projection was relatively close, within a few thousand workers or a few percentage points. For example, the occupation of paralegals and legal assistants was projected to be the fastest growing between 1988 and 2000, with a projected rate of increase of 75 percent. It actually increased 71 percent. The high degree of accuracy suggests that it was correct to assume that more paralegals would be hired because of an increase in the demand for legal services and because paralegals often do many of the same tasks that lawyers do but for lower fees.

Among the 20 projected fastest growing occupations, 3 of the 5 that did not grow much faster than the average still had positive growth rates. Others that were projected to have slow growth actually increased faster than projected. An analysis of fast growing occupations suggests that the basic growth assumptions were usually accurate, but their effects on employment were either under- or over-estimated.

For example, increased use of computers and other office equipment led to a projection of much faster than average employment growth for data processing equipment repairers. However, that occupation's growth may have been limited because equipment improvements led to fewer breakdowns. It is possible that the use of computer equipment in offices increased less than assumed or that the quality of the technology proved higher than assumed. Either way, the fundamental assumptions of growth for this occupation were correct: employment of data processing equipment repairers grew, but at an average rate.

Among the 20 occupations that actually grew fastest, all had been projected to grow, and 15 were projected to grow either faster or much faster than the average. For each occupation, actual growth rates were significantly higher than projected, again showing the tendency toward conservative projections.

The occupation that had the fastest employment growth between 1988 and 2000 was social and human service assistants. Its employment was projected to grow 45 percent, much faster than the average, but actually grew 141 percent—over 3 times as fast. Even though the growth trend was identified, BLS analysts underestimated the demand for workers who would be needed to administer job training and other programs, including those for the poor, elderly, disabled, or mentally ill. A change in welfare laws in the 1990s, from benefits-based programs to work-based initiatives, required an increase in the number of job-training facilities. That was a main reason for the large underestimate of employment growth.

Many of the projected and actual fastest growing occupations were either professional or service occupations. Most of the occupations were in healthcare or social services, reflecting the trend of high growth in these areas because of a growing and aging population. In particular, employment in the occupations of emergency medical technicians and paramedics increased significantly more than projected.

Another area with fast growth rates was amusement

and recreation services. Among the occupations in which employment increased rapidly were actors, directors, and producers; counter and rental clerks; ushers, lobby attendants, and ticket takers; and amusement and recreation attendants. The large increases in these occupations are attributable to the strong growth in leisure activities, reflecting a rise in the population that had growing incomes and leisure time.

A third group of occupations among the 20 projected or actual fastest growing included some administrative support occupations. Employment of bill and account collectors was the fourth fastest growing, due to increasing consumer debt and creditors' desire—especially in healthcare—to collect their payments. Shipping, receiving, and traffic clerks also had rapid employment growth. Slower than average growth was projected due to increased automation in the packaging and shipping processes, but the effects of automation on this occupation either were outpaced by economic growth or were overestimated. Employment of teacher assistants also grew more rapidly than expected because of increasing school enrollments.

**Declining occupations.** Just as the basic assumptions were accurate for fast-growing occupations, assumptions also were accurate for occupational declines. For example, of the projected 20 fastest declining occupations, more than half actually declined, with 7 of the occupations among the fastest declining. And like those of fast-growing occupations, projections of declining occupations were conservative. Rates of decline in most occupations were much higher than projected.

Unlike the varied reasons for differences between actual and projected fast-growth occupations, however, one reason stands out in comparing actual with projected declines: the underestimated effects of technological advance on employment. The decline in employment of railroad brake, signal, and switch operators, for example, was more rapid than projected because of an increased use of computer-controlled train cars. These cars operate the brakes, doors, alert systems, and signals automatically, thus reducing the number of workers needed to operate a train.

Gains in technology also were responsible for fast employment declines in textile occupations, such as garment sewing machine operators and precision shoe and leather workers and repairers. Other groups of occupations with fast declines in employment because of technology include some administrative support workers—such as word processors and typists—and machinery assemblers, installers, and repairers—such as precision aircraft assemblers.

Unexpected changes in technology affected occupations in ways that could not be anticipated at the time the projections were made. In many cases, new technology caused employment declines in occupations that were projected to grow. During the 1990s, the most significant technological advance was the Internet, from which emerged electronic commerce, or e-commerce. The Internet and e-commerce allow consumers to research and purchase an assortment of goods and services directly from suppliers, thereby reducing the need for buyers and sales agents to act as go-betweens. One group of occupations whose employment was adversely affected by the Internet was sales occupations, specifically wholesale and retail buyers, except farm products; purchasing managers; insurance sales agents; real estate sales agents; and travel agents.

The rise of the Internet had a positive effect on employment growth in some occupations, however. Employment of telephone and cable TV line installers and repairers was projected to be among the top 20 fastest declining occupations but actually grew more than 62 percent between 1988 and 2000. Increased demand for Internet access through telephone and cable TV wires was the main cause for the employment increase in this occupation. But growth also stemmed from telephone and cable TV companies' desire to upgrade their networks quickly in an effort to remain competitive.

Occasionally, the effects of technology on employment were overestimated, as was the case with precision electrical and electronic equipment assemblers and electrical and electronic assemblers. These two occupations were projected to have the first and second fastest rates, respectively, of

employment decline—but both occupations actually grew over the projections period. Technological advances or increases in automation most likely did not occur as fast as anticipated. It is also possible that fewer than expected jobs were lost to workers abroad.

#### **Opportunity descriptors**

In addition to providing a growth descriptor to characterize future employment growth, the outlook section of each *Handbook* statement describes opportunities and competition for jobs. Where applicable, information is presented on technological or demographic changes affecting industries in which an occupation is concentrated or on the impact of educational backgrounds on employment prospects.

The following descriptors were used in the 1988-2000 *Handbook* to give readers an idea of how difficult it might be to get a job in a particular occupation:

	Projected job openings
Opportunity descriptor	compared with jobseekers
Excellent	Much more numerous
Very good	More numerous
Good or favorable	About the same
May face competition	Fewer
May face keen competition	Many fewer

Such statements were perhaps most significant when occupations' expected job competition differed from projected employment growth. For example, employment of private detectives and investigators was projected to grow much faster than average. However, as the opportunity descriptor correctly projected, keen competition existed in 2000 because the challenging work and relatively high salaries attract more jobseekers than there are openings.

#### **Growth versus opportunity**

As the *Handbook* discusses in job outlook sections, an occupation's rate of growth is not necessarily the best indicator of job opportunities. Many times, a small, fast-growing occupation yields fewer new jobs than a large, slower growing one that has high job turnover or a high proportion of part-time workers. For example, social and human service assistants, a relatively small occupation, was the fastest growing occupation, growing 141 percent to gain 166,000 new jobs between 1988 and 2000. In that same period, however, the large occupation of cashiers created the most new jobs—979,000—despite its comparatively slower growth rate of 42 percent.

Dominating the list of occupations with the largest job growth were service occupations, especially those in healthcare, education, and food services. Most of the growth in these occupations is attributed to economic and population growth. In addition to cashiers, other occupations with large job growth were truckdrivers, registered nurses, janitors and cleaners, retail salespersons, food preparation workers, waiters and waitresses, secondary school teachers, and teacher assistants.

Similarly, occupations with the fastest declines in employment did not necessarily have the largest numerical declines. Farmworkers, for example, while not among the occupations with the fastest employment declines, were among the occupations with the largest job declines. Technology gains and new laborsaving machinery were the main reasons for the decline, along with increased farm consolidation in recent years. Other occupations with large numerical declines in employment were service station attendants, childcare workers in private households, and secretaries, except legal and medical.

### Sources of error

Many errors in projections for detailed occupations are linked to faulty assumptions about changes in total industry employment or erroneous analytical judgments about the mix of occupations that industries would use. The first kind of error is called an industry assumption error. The second kind of error is known as a staffing pattern assumption error.

As past evaluations have indicated, good occupational projections depend on good industry projections. And as discussed previously, the impact of some factors, such as technological change, often is underestimated when projections are developed. For more information about developing the projections and, subsequently, choosing occupations for evaluation, see the box on page 9.

#### **Industry assumption errors**

Errors in employment projections for the educational services, textiles, and legal services industries affected the employment projections for occupations in those industries. In the educational services and textile industries, employment change was underestimated; in legal services, employment change was overestimated.

Between 1988 and 2000, the educational services industry grew almost 3 times as fast as projected. The main reason for the rapid growth was a faster than expected increase in school enrollments. The industry projection affected estimated employment for occupations concentrated in education, and employment of teachers at all levels was underestimated. In addition to teachers, other occupations in educational services for which employment was underestimated include counselors, education administrators, and school busdrivers.

The largest underestimate of employment was for special education teachers, whose numbers grew almost 4 times faster than projected. Learning disabilities were identified and diagnosed at earlier ages, more legislation was passed emphasizing training and employment for persons with disabilities, and educational reforms required stricter graduation standards for students. All of these trends contributed to the rapid employment growth of special education teachers.

Employment change in textile industries, such as apparel and knitting mills, also was underestimated. Employment in these industries was projected to decline, but actual rates of decline were about 3 times faster than projected. The main assumptions behind the projected decline in employment were the effects of laborsaving machinery and the shift of textile jobs from the United States to countries with lower labor costs—and both were underestimated. As a result, employment declines in occupations such as garment sewing machine operators and textile machine setters and setup operators were significantly underestimated: employment of garment sewing machine operators, for example, declined almost 4 times as fast as projected.

An overestimate of the legal services industry, which grew half as fast as projected, led to an overestimate of

employment in legal occupations such as lawyers, legal secretaries, and, to a lesser extent, paralegals and legal assistants. A growing number of businesses, such as accounting and management consulting firms, began offering legal advice on topics such as tax law and employee benefits, contributing to a slower than projected employment growth in legal services. And to reduce legal fees, clients found legal advice by hiring lawyers on a short-term contract through personnel staffing firms.

#### **Staffing pattern assumption errors**

In addition to incorrect assumptions about total industry employment, incorrect judgments about the mix of occupations each industry would use contributed to errors in employment projections. These errors—such as under- or over-estimating the effects of technological change or of trends such as the use of contract workers are most observable in healthcare occupations. The errors were related: employment grew more slowly than projected in health diagnosing occupations while increasing more quickly than projected for health technicians and technologists, health assessment and treating occupations, and health service occupations.

Health diagnosing occupations include physicians, optometrists, and dentists. Examples of health technicians and technologists, health assessment and treating occupations, and health service occupations are physician assistants, dental hygienists, occupational therapists, and emergency medical technicians and paramedics. It was assumed that the relative number of physicians, optometrists, and dentists working in offices of health practitioners would

### Projections framework and selecting occupations to evaluate

Employment projections are developed using the Bureau of Labor Statistics (BLS) projections model. In addition to estimating future employment, the model also projects the size and composition of the labor force, the level of gross national product, and the total output of goods and services by industry. The projections reflect specific assumptions concerning, and targets for, major economic variables—such as the unemployment rate and defense expenditures—along with the knowledge and judgment of BLS economists who analyze factors that affect employment growth.

Occupational employment projections for the 1988-2000 period were developed within the framework of an industry-occupation matrix. The matrix described how employment in each occupation was distributed across industries, and vice versa. It contained data for 258 detailed industries, 9 major occupational groups, and nearly 500 detailed occupations.

#### Where the data came from

Data used to derive the 1988 and projected 2000 matrices came from a variety of sources. For every set of projections created, the predominant source of information about occupational employment within industries is the Occupational Employment Statistics (OES) survey. Each OES survey takes 3 years to complete. For the 1988-2000 projections, OES data from 1985, 1986, and 1987were used to estimate the distribution of occupational employment in each industry covered by the survey. These occupational distributions, called staffing patterns, were applied to total industry employment figures from the BLS 1988 Current Employment Statistics (CES) survey.

In part because the OES and CES surveys are of establishments, neither survey includes workers who are self-employed, unemployed, or in certain industries. To develop the occupational distribution patterns for these workers, data from the 1988 Current Population Survey (CPS) were used. The CPS, a survey of households, provides estimates of self-employed and unpaid family workers by occupation and also gives data on workers in agriculture; forestry; fishing, hunting, and trapping; and private households—industries not covered by the OES survey. Occupational distribution patterns for the Federal Government, which are also excluded by the OES survey, were derived from data provided by the U.S. Office of Personnel Management. For some occupations, data from other sources were used—such as data on teachers from the U.S. Department of Education's National Center for Education Statistics.

### How occupations were selected for evaluation

BLS evaluated projections only for occupations for which OES data from the "base year" of 1988 and "target year" of 2000 could be compared. One of the difficulties in evaluating the 1988-2000 employment projections was the 2000 revision of the Standard Occupational Classification System (SOC), the Federal Government's primary catalog of occupations. With the revision, the titles and content of the major occupational groups and many detailed occupations in the 2000 SOC are substantially different from those in the previous SOC. Some major groups were renamed, combined, or reorganized. Some individual occupations were renamed or reclassified into different major groups; many new occupations were added. Some occupations were combined; others were separated into more detail.

Because of these changes, the occupations and major groups reflected in the 2000-10 national employment matrix are not comparable with those in the 1988-2000 employment matrix. SOC revisions caused comparability problems across occupations and major groups between 1988 and 2000. These incompatibility problems had to be addressed to evaluate the projections. For this evaluation, 1998 staffing patterns, developed before the SOC revisions, were applied to industry employment totals for 2000 to create comparable 2000 data. As a final step, the original 1988 employment figures were reconfigured to the 1998 occupational structure, adjusting for any occupations that had been added to the matrix over time.

After the data were prepared, occupations that met certain criteria were selected for evaluation. The projections were analyzed for all 9 major groups and 338 of 491 detailed occupations. Eliminated from the evaluation were occupations that had definitions that were not consistent between 1988 and 1998, employed fewer than 25,000 workers in 1988, or were in a residual, catchall category, such as "all other computer specialists." The numerical cutoff was the same as that used to produce the list of occupations published in the November 1989 *Monthly Labor Review* article about the 1988-2000 employment projections.

decline because of an increase in group medical practices that rely more heavily on health support staff such as nurses, technicians, and clerical support. Often, these health support workers perform, at a lower cost, some of the routine tasks usually performed by physicians. A growing number of outpatient health service facilities also rely on these lower skilled healthcare workers. The trend was correctly assumed, but its effects were underestimated.

Employment growth was slower than expected among the highly skilled health diagnosing occupations and faster than expected among the lower skilled health technician and assessment and treating occupations. For example, dentists, dental hygienists, and dental assistants all were projected to have average employment growth. However, employment of dentists declined slightly while that of both dental hygienists and dental assistants grew much faster than average. Employment in the health diagnosing occupations was overestimated, and the growing reliance on lower skilled healthcare workers to carry out more routine tasks appears to have been underestimated because of the overly conservative growth projections for these occupations.

### Industry and staffing pattern assumption errors

For some groups of occupations, inaccuracy in the projections resulted from both faulty assumptions about industry employment and mistakes in analytical judgment about the use of occupations. Projections in employment of protective service occupations and engineers illustrate this point.

Most protective service occupations—including firefighters, police patrol officers, detectives and criminal investigators, and correctional officers—are in State and local governments. Employment of these workers grew faster than projected between 1988 and 2000 because of population growth and increasing crime rates. State and local government employment also grew faster than projected, an example of industry assumption error, and governments employed more protective service workers than expected, an example of staffing pattern assumption error.

Workers in other protective service occupations, such as guards and private detectives and investigators, are employed by both government agencies and private businesses such as department stores.

Errors for these protective service occupations are mainly attributable to errors in staffing patterns because of higher than anticipated growth in employment of

contract workers. Many businesses and government agencies that previously employed security guards or private detectives directly began to hire them instead through security staffing service firms to reduce costs. As a result, there was a shift in employment away from traditional employers, such as retail establishments and government, and toward business service firms specializing in security services. Because this shift was not anticipated, projections were underestimated.

Employment growth of engineers was projected to be average or faster than average from 1988 to 2000, but engineers actually showed little employment growth or declined. In an example of industry assumption error, research and development expenditures declined faster than expected during the 1990s as the end of the Cold War led to declines in defense spending and the hightechnology industries related to defense, such as communications equipment and electronics. The decline of the U.S. defense industry also opened the door to increasing competition from abroad, particularly in aerospace manufacturing, leading to further employment declines especially for aerospace engineers. Declines in research and development expenditures and growing international competition also forced companies to cut costs.

One cost-cutting measure was to contract with engineering consulting firms. As a result, employment of engineers shifted away from manufacturing industries, such as chemicals and electronic components, and toward business services firms. Also, increased use of technology such as computer-aided design allowed workers in lower-skilled occupations, such as electrical and electronic technicians and technologists, to perform some of the tasks of engineers. This changed the mix of occupations that industries used.

Another reason for errors in staffing patterns for engineers was a change in the classification system of occupations that added new engineering occupations after the projections were completed in 1988. For example, computer engineers were classified as electrical and electronics engineers for the 1988-2000 projections cycle. But in 1989, computer engineers became a separate occupation, taking some of its employment from electrical and electronic engineers. This accounts for some of the sharp decline in employment among electrical and electronic engineers.

#### ----- Final analysis

As past evaluations have shown, BLS occupational projections tend toward conservatism. Projected employment for the largest number of occupations was concentrated in the average growth range, whereas most actually grew faster or declined. Employment in occupations projected to have the most rapid employment growth was underestimated, and occupations projected to experience little growth or to decline experienced greater declines than anticipated.

The BLS tendency toward conservatism does not mean that the 1990-91 *Handbook*'s information on job outlook was of no value. In fact, assumptions made about factors affecting employment growth were often correct, even if their impact was not fully anticipated. The direction of employment change was projected correctly for roughly 70 percent of the occupations in this evaluation, and an increase was projected for all but 31 of the 234 occupations for which employment actually grew between 1988 and 2000. However, the effects that technological change and other factors had on future employment within industries—such as the organizational structure of businesses and shifts in the demand for specific goods and services—generally were underestimated.

This evaluation also reconfirms that good occupational projections depend on good industry projections. Analysis of the outlook for detailed occupations is directly tied to the outlook for the industries in which they are concentrated. As a result, incorrect projections for industries, such as educational services, led to incorrect occupational projections. Since the 1940s, BLS has prepared job outlook information for career guidance counselors, education planners, students, and others. Over time, BLS has taken steps to resolve the causes of error in, and increase the reliability of, occupational projections. Adjustments have led to changes in the way assumptions are incorporated, to eliminate some of the bias toward conservatism and to improve the industry projections.

Regardless of how carefully the assumptions are prepared, however, some events—such as the reduction in defense spending over the 1990s—remain impossible to foresee. And the rapid advance of technology makes its future impact on occupations—for example, the effect of Internet technology on emerging occupations—increasingly difficult to predict.

Still, in the 1990-91 *Handbook*, the growth descriptors for 189 occupations—55 percent of those evaluated were either on target or one category away. And the direction of employment change was correctly projected for 70 percent of the occupations. Thus, users of BLS employment projections should continue to have confidence in the value of BLS job outlook information.

### A note about the table

The accompanying table lists projected and actual employment totals, percent changes, and growth descriptors for all 338 occupations included in this evaluation. The table compares growth descriptors projected for 1988-2000, the basis for the 1990-91 *Occupational Outlook Handbook*, with descriptors based on the actual change in employment.

The first three columns show employment in each occupation in 1988, projected for 2000, and actually attained in 2000. Data for actual 1988 and projected 2000 employment are from the 1988–2000 National Employment Matrix, published in 1989; however, they have been reconfigured to the 1998 occupational structure. The actual 2000 employment numbers were derived for purposes of this evaluation by applying the 1998 staffing patterns to the 2000 industry totals.

The next two columns list the percent change in each occupation as projected and as actually occurred.

The final two columns compare the growth descriptor of the original projection with the descriptor for actual change.
